December, 1983

Plant Science Pamphlet #73 ANNUAL PROGRESS REPORT

# CENTRAL CROPS AND SOILS RESEARCH STATION

### HIGHMORE, SOUTH DAKOTA

#### BRIEF HISTORY

The Central Research Station Advisory Board met in Highmore, December 6, 1983 to discuss research on the station. At this meeting, Scott Ingel of Beadle County was elected president and Dick Fadgen of Beadle County secretary for 1984. New advisors to the Advisory Board for 1984-87 are Val Goetz of Faulk County and Lynn Metzinger of Hughes County.

Due to the late spring, the soil preparation and planting of crops were delayed till late April in 1983. The planting of small grain and other crops progressed smoothly after the soil dried down enough. Many of the small grain crops were shorter than usual due, in part, to the cool soil. Some flooding reduced stands and in other areas drown out the crop completely. In 1983, 16.5 inches of moisture were received on the station. The long time average rainfall for April through October is 17.2 inches. Except for the months of May, June, and September, the precipitation was below normal. There were 20 days in July and 28 in August when the air temperature was 90°F or higher.

An evening crop tour was conducted on the station July 10th to view the various research experiments being conducted. In 1984, an evening tour is scheduled for July 10 at 6:30 PM. The winter meeting is set up for December 11th with an alternate date of December 18th, in case of severe weather conditions, at Highmore.

NOTE: This is a progress report and, therefore, the results presented are not necessarily complete nor conclusive. Any interpretation given is strictly tentative because additional data from continuation of these experiments may produce conclusions different than those of any one year. These data reflect the 1983 growing season. Of the second second

#### 1983 Crop Season

Total rainfall for growing season by months with their departure from long-time average on Central Research Station, Highmore, S.D.

| Rainfall  | Inches | Normal | Departure* | Greatest Day | Date |
|-----------|--------|--------|------------|--------------|------|
| April     | 1.13   | 1.87   | -0.74      | 0.20         | 12   |
| May       | 3.05   | 2.55   | +0.50      | 0.95         | 12   |
| June      | 5.75   | 3,97   | +1.78      | 1.70         | 12   |
| July      | 2.13   | 2.54   | -0.41      | 1.25         | 28   |
| August    | 1.60   | 3.45   | -1.85      | 0.50         | 20   |
| September | 1,90   | 1.61   | +0.29      | 0.60         | 10   |
| October   | 0.95   | 1.25   | -0.30      | 0.30         | 1    |
| Total     | 16.51  |        |            |              |      |

Long term average 17.24 inches April through October.

Number of days during month with temperature 90° or above: June 3; July 20; August 28; September 9.

Last frost - Spring (May 15) First frost - Fall (September 21) Frost free period - 128 days

#### CROP ROTATION - SOIL MOISTURE USAGE RELATIONSHIP 1983

#### Q. Kingsley and M. Volek

#### OBJECTIVE OF EXPERIMENT:

1. To compare various crops with different maturities for soil moisture usage and yielding ability under similar soil and climatic conditions.

DISCUSSION:

Table 1

Crops chosen for this experiment are of different maturities. Barley, pats and wheat are the shorter season crops and corn, grain sorghum and sunflowers are the long season crops. Planting and harvest dates are the same as \* Inches used period below Table 1.

The sunflowers in this crop rotation study were severely damaged by birds and were not harvested for yield. The soil moisture usage of the crop was taken to provide continuity in the experiment.

RESULTS: Central Research Station, Highmore, S.D. 1983

#### HAY, HAYLAGE AND SILAGE PRODUCTION Central Research Station, 1983 Q. Kingsley and M. Volek

TITLE: Dry Matter Production for Small Grains, Millet and Forage Sorghum.

**OBJECTIVES OF EXPERIMENT:** 

1. Compare various crops for dry matter production.

2. Obtain regrowth data after first harvest for green chop or haylage.

DISCUSSION:

Four oat varieties of various degrees of maturity were used for this study. The earliest variety, Nodaway 70, when considering all three states of cutting, produced the most tonnage of dry haylage. Grain yield of this variety was not as high as the other three, but protein in the grain was better. Highest yields in tons per acre occurred during the dough stage as indicated in Table 2.

#### **RESULTS:**

| 100                     | -            | 1            | Vield In   | tons per<br>Late | acre          | Grain   |              |         |

| Nodaway 70<br>Medium E. | 5.1          | 10.7         | 6.1        | 10.6             | 5.0           | 9.5     | 68.6         | 15.4    |
| Burnett<br>Medium       | 5.1          | 12.2         | 5.4        | 12.0             | 5.1           | 11.3    | 72.4         | 13.9    |
| Lancer<br>Medium        | 5.4          | 12.5         | 5.0        | 10.9             | 4.7           | 12.1    | 72.4         | 14.6    |
| Benson<br>Medium L.     | 5.4          | 13.0         | 5.4        | 12.4             | 4.8           | 11.4    | 77.4         | 14.4    |
| Average                 | 5.25         |              | 5.48       |                  | 4.90          |         | 72.7         |         |

Table 2. Small Grain Haylage, Tons of Ory Matter\* (DM) per acre at stages of maturity. First planting May 5, 1983.

Hay (88% OM); Haylage (50% DM); Silage (33% OM).

\* To determine yields of hay, haylage or silage: Divide tons of DM by percent DM in hay, haylage or silage. Example (DM average for dough if divided by 0.88 equals tons of 12% moisture hay, etc.)

Harvested: Listed above under column heading.

#### DISCUSSION:

The percent protein of the milk and dough stages were consistent with those shown in Table 2 but protein in the late dough haylage was lower. Weather conditions at this time had a detrimental effect on the crops. Grain yields dropped some and production was about the same for all varieties.

#### **RESULTS:**

| maturity. Second pranting may 25, 1905. |                |              |               |              |                       | The second second |             |                     |

\*Refer to Table 2 to determine yield at various stages \*\*Harvested: Listed above under column heading

#### FORAGE SORGHUM - MILLET

## DISCUSSION:

The tonnage produced from these various forage crops reflects the environmental conditions during 1983. Yields were taken at the green chop stage August 22, and at silage cutting time, September 10th. Each entry, including Sudan grass, was put into a Type\* category and listed according to yield. The crops in Tables 4 and 5 were planted in 30 inch rows and those in Table 6 were planted using a grain drill. Corn was harvested at both stages, green chop and for silage.

Weeds were the main problem in the forage crops this year, particularly grassy types.

.... The forage sorghums were planted June 3rd in a well prepared seedbed.

Table 6. Dry Matter Production of Millets, Tons of Dry Matter per acre\*, Foxtall Types. Central Research Station, 1983.

\* All yields are reported on an oven dry basis.

\*\* Means with the same letter are not significantly different.

#### DISCUSSION:

This study was planted June 3 and harvested August 3. These plantings were solid seedings using a grain drill with 7<sup>st</sup> spaced openers. The planting rate was 15 pounds per acre. Rainfall during this period was 7.8 inches.

There were no statistical differences in yield due to stand variabilities. There was a significant reduction in yield from dry matter production in 1982. High moisture and temperatures seriously hindered the plant growth and stooling ability of the crop. Only one cutting of all millets was taken in 1983. Yields and other data are presented in Table 6.

#### TILLAGE AND PLANTING METHODS, 1983 Q. S. Kingsley and M. Volek

TITLE: Tillage and Row Crop Planting Methods.

### **OBJECTIVES:**

- Compare various row crop responses to tillage methods, namely: chisel plow, plow and no till.
- Compare conventional, lister and furrow type plantings using corn, grain sorghum and sunflowers.
- 3. Determine soil moisture usage for each crop, planting and tillage method.

#### DISCUSSION:

This experiment was started in 1981 on a summer fallowed piece of ground. A 4 acre piece was planted to wheat in preparation for the no till, plow and chisel plow phase of this experiment in 1983. Yields were taken from all crops to determine if planting method had much effect as shown in Table 7.

### SAFFLOWER TRIALS Q. Kingsley and M. Volek

#### TITLE: Safflower Trials and Row Spacings

#### **OBJECTIVES:**

What entry performs most satisfactorily in this area of South Dakota?
Will various row spacings affect the yield and physical condition of the crop?

#### DISCUSSION:

Two row spacings, 7 and 14 inch, were used to plant safflower this year. The planting rate was 20 pounds per acre. This seemed to be adequate for the type of a season which occurred. The crop was planted April 22 and harvested August 23. There was 11.6 inches of moisture received during this period.

Safflower should be planted about the same time as wheat. The plant will produce some top growth and then seem to go dormant. It is during this dormant period that roots are growing and when a certain stage is reached the top will elongate. Late plantings set the plant back and roots are not as extensive in the soil. The results of this study are shown in Table 8. One of the varieties exceeded the 40 pound test weight.

#### Table 8. Safflower Variety Row Space and Yield Study. Central Research Station, 1983.

#### Spring Wheat Breeding Highmore

F. A. Cholick, K. W. Sellers, and G. W. Buchenau

The results of the spring wheat advanced yield trial are presented in Table 9. This trial is conducted to compare the best experimental lines from the breeding program with selected check varieties to identify new varieties. Due to environments varying from location to location as well as year to year, this nursery is grown at 9 locations throughout the spring wheat production area.

Grain yields in 1983 were similar to 1982 and considerably greater than the long-term average. This was reflected in the number of days from planting to heading which was approximately 5 days longer than normal. Test weights were a little low, indicating some stress late in the growing season.

A seed treatment study with two varieties, Olaf and Centa, and treatments of Benlate T, Vitavax200 and an untreated control was conducted to evaluate the effects of seed treatments on yield. Sound seed samples with little or no scab or loose smut were used to determine the effects of seed treatment in the absence of these diseases. The seed treatments did not produce a significant effect on grain yield at Highmore or at any of the five sites where this experiment was grown.

The plots were planted on April 22, 1983 at a rate of 75 lbs/A with fairpoor top soil moisture. Soil tests were taken and all experiments were fertilized for a 45 bu/A yield goal. Experimental site is in a wheat-fallow rotation. There were little or no problems with weeds or diseases. Harvest was completed on August 4, 1983.

Winter Wheat Herbicide Comparison

W. E. Arnold, P. Johnson, L. Wrage

Effectiveness and crop tolerance are major considerations when selecting herbicides for winter wheat. Crop growth stage is an important factor in evaluating effects of herbicides on winter wheat.

#### OBJECTIVE

The purpose for the experiment was to evaluate the performance of labeled herbicide treatments applied to winter wheat at three growth stages.

#### PLOT INFORMATION

The plots were established in winter wheat which has been planted in the previous year's oat stubble. Plots were 10' x 50'; 4 replications. Soil was a well drained loam with 3.7% organic matter and 6.9 pH.

All herbicides were applied with a plot sprayer calibrated to apply 20 gpa at 39 psi pressure. Herbicide treatments were applied May 4 (2-3 new leaves), May 18 (early jointing) and June 3 (late boot). A light kochia and wild buckwheat infestation was present. Seedling weeds evident in early season failed to develop to the extent visual weed control evaluations could be estimated.

Plots were harvested using a plot combine. Harvest data are presented in Table 10.

#### RESULTS

Yield for 10 of the 14 herbicide treatments was greater than the untreated check. This indicates most treatments had little injurious effect on the crop at the stages treated or that the crop recovered as the result of favorable weather following application. At recommended growth stages, no treatments significantly reduced yields. Dnly 2,4-D ester at the late growth stage significantly reduced yield. This suggests careful evaluations before applying 2,4-D ester during the critical late boot stage. Dther alternatives such as 2,4-D amine, or bromoxynil + MCPA may be considered if they will control the weeds present. Dicamba (Banvel) or picloram (Tordon 22K) combinations have shown adverse crop effects in other tests when applied at stages beyond those recommended. Less favorable mid-season weather may result in reduced crop tolerance from other treatments.

Both nematicide and fungicide treatments significantly increased alfalfa stands at two locations (Table 12). These results in combinatio with those obtained in previous years' studies provide additional evidence that nematodes and fungi are involved in alfalfa stand failures.

#### Oat Breeding & Testing D. L. Reeves

-19-

Ē.

At the Highmore station, the oat breeding project had three different tests nin 1983. Two of these tests contained advanced lines from material which we have developed. We anticipate that at least two: of these will be given to the Foundation Seed organization for planting this next spring. As soon as the seed is increased to a sufficient volume, they would then be released to farmers.

For several years we have also grown our Tristate test at Highmore. This is a cooperative testing plan, with the breeders in North Dakota and Minnesota, Each of us can submit up to 10 selections from our early generation material that we think has good potential. Each state has three testing locations so each line is tested over a wide geographic area. From the results of this test, we decide which ones look good enough to continue testing or to put in the regional test which is coordinated by the USDA.

In addition, we also had five of our most advanced lines entered in the Standard Variety Oat trials which are grown statewide. Two of these are being 12 22 increased with hopes to release one in 1984 and another in 1985.

#### Winter Wheat Program at Highmore J. L. Gellner

13.40

Approximtaely 250 advanced winter, wheat lines were grown at Highmore in der ' rob 1983, along with both Northern and Southern Regional Nurseries. Due to the mild winter, no winter-kill was recorded in any research plot. 125 20

:4:

· · · · · ·

This fall 60 of the advanced winter wheat lines were planted again for further yield testing. In addition, approximately 200 early generation bulk plots were planted to help in selection for lines adapted to Highmore ..... . . . . conditions. Also, winter barley bulks were planted to test for winterhardiness, in barley.

#### Chickpea Research

#### Arvid Boe and Solomon Tuwafe

#### Introduction

Chickpeas (Cicer arietinum), also called garbanzo beans, are a large-seeded drought tolerant legume currently being produced in India, Pakistan, Spain, Algeria, Mexico, and the U.S. Most of the U.S. production (3500 tons/year) is in California, and annual imports from Mexico have averaged over 10,000 metric tons. Decreasing production in California and Mexico has encouraged recent research in Idaho, Montana, Washington, and Saskatchewan on the adaptability of chickpeas to those climates and cropping systems. The research work in those regions has centered around agronomic evaluation (e.g., weed control, planting rates and dates, harvest methods) of a few commercial varieties. South Dakota research has focused on the initial screening of vast numbers of germplasms from worldwide sources. ICARDA (International Center for Agricultural Research in Dry Areas) has assisted the South Dakota program by providing seed from well over 1000 lines. Trials in South Dakota and other states have shown that chickpeas are adapted to several semiarid regions of the continental U.S. Market quality and price are determined by seed size and color. At present, the major market in the U.S. is for the "salad bar" garbanzo bean, which is the large cream-colored type. However, extensive variation for seed color (white, cream, green, red, brown, black) and seed size can be found in the present South Dakota germplasm stock.

In 1983, several experiments were conducted at Brookings, Rapid City, and Highmore. Results of the different trials at Highmore are presented below.

#### 1983 Chickpea Screening Nursery

A total of 68 advanced breeding lines obtained from ICARDA were evaluated. The nursery was planted on April 22, 1983 in 10 ft single row plots with 2 ft interrow spacings. Out of the 68 entries, only 2 failed to germinate. Otherwise stands were acceptable to excellent and most of the lines exhibited normal growth and uniform maturity. Plots were harvested on August 16, 1983. Yields ranged from 822 to 4211 kg/ha. Eighteen lines yielded greater than 3000 kg/ha (Table 13) while only 5 lines averaged less than 1000 kg/ha.

#### 1983 Chickpea Adaptation Trial

Sixteen lines originating from eight different countries were planted on April 22, 1983 in a 4-replicate randomized complete block design. Plot size was 10 by 4 ft with one foot spacing between rows. Spacing between plants within rows was approximately 4 inches. The two middle rows of each plot were harvested for seed yield on August 15, 1983. Seed yields ranged from 617 to 1938 kg/ha. The four highest yielding lines were of Indian origin (Table 14). Data on stand indicated a positive association between yield and stand.

#### 1983 Chickpea International Yield Trial

The trial consisted of 24 entries planted in a 4-replicate randomized complete block design on April 22, 1983. Interrow and intrarow spacings were one foot and 4 inches respectively. The trial was harvested on August 16, 1983. The importance of a good stand for obtaining high yields was clearly evident in

this trial (Table 15). Yields ranged from 356 to 2455 kg/ha. The highest seed yield (2455 kg/ha) and percent stand (70%) was exhibited by ILC 480. Sixteen entries outyielded the check entry (1194 kg/ha) and 12 entries produced higher yields than the overall trial mean.

### 1983 Large Seeded Chickpea International Trial

Nineteen large-seeded entries, with one 1982 SD selection as a check, were planted in a replicated randomized complete block design on April 22, 1983. Each plot consisted of four rows with 1 foot and 4 inch interrow and intrarow spacings, respectively. The middle two rows of each plot were harvested on August 15, 1983. Yields ranged from 1094 to 2833 kg/ha (Table 16). The largest seed (45 grams per 100 seeds) was produced by a Spanish entry (ILC 112) with an average seed yield of 1672 kg/ha. Eight entries outyielded the check for seed yield (2206 kg/ha) and seed size (20 grams per 100 seeds). The lowest yield (1094 kg/ha) was obtained from a Tunisian entry (ILC 629). As was observed in the other trials, stand played a very important role in seed yield.

#### 1983 Chickpea Internation F3 Trial

This trial consisted of 15 entries of F<sub>3</sub> generations selected in Syria. The main objective of this trial was to identify adapted segregating material to be used as breeding stock for South Dakota conditions.

Sixteen entries, including one 1982 SD selection as a check, were planted in four-row plots in a replicated randomized complete block design on April 22, 1983. The trial was harvested on August 16, 1983. All entries outyielded the check (Table 17). Yields ranged from 716 to 1461 kg/ha.

#### South Dakota Selections Trial

Ten entries chosen because of high seed yields at Highmore and Brookings in 1982 were evaluted in this trial.

The trial was planted April 22, 1983 in four row plots in a 4-replicate randomized complete block design with interrow and intrarow spacings of 1 foot and 4 inches, respectively. Plots were harvested on August 15, 1983.

The highest yield of 2739 kg/ha was produced by a Jordanian entry (ILC 1932). ILC 1934 was the second top yielder with relatively large seed size (34.2 grams per 100 seeds). The lowest yield was recorded for breeding material, FLIP 81-58, provided by ICARDA. However, the other two breeding materials, FLIP 81-34 and FLIP 11-64, were found to yield 1967 and 1928 kg/ha, respectively. Yields ranged between 1772 and 2739 kg/ha (Table 18).

#### Conclusions

Yields of the top-yielding lines at Highmore have been as high or higher than those reported from Idaho, Washington, Montana, California, and Saskatchewan. Data collected in South Dakota over the past three summers indicated that several of the germplasms evaluated are well-adapted to South Dakota conditions, particularly the western two-thirds of the state. The large-seeded cream-colored types have performed well at Highmore, but high yielding smaller seeded lines with dark seed color have also been identified. Those lines are high in protein (25%) and energy (700 calories per cup) and offer tremendous potential for export to areas where animal protein is limited and as a high protein, high energy livestock feed supplement in this country.

- Future plans of the program are:
- 1) to increase seed of promising lines
- 2) continue to screen and evaluate additional germplasms and breeding stocks.
- initiate research on cultural practices applicable to South Dakota farms and cropping systems.

#### Grass and Legume Forage Grop Research Arvid Boe and Richard Wynia

Smooth bromegrass, crested wheatgrass, and intermediate wheatgrass forage yield trials planted in 1981 (see descriptions in 1982 Annual Progress Report) were harvested once in 1983. Dry matter forage yields for three crested wheatgrass entries (Ruff, Nordan, and SD 714) harvested on June 10 were not significantly different and the overall trial mean was 1.8 tons/acre. A significant difference for forage yield was found among three intermediate wheatgrass entries harvested on July 19. SD 54 (an experimental synthetic variety developed at SDSU) significantly outyielded Oahe and Slate. Dry matter forage yields for SD 54, Slate, and Oahe were 3.6, 2.9. and 2.7 tons/acre, respectively. Dry matter forage yields of Lincoln and Cottonwood bromegrass harvested on July 19 did not differ and the overall trial mean was 2.4 tons/acre.

Two grazing-type alfalfa forage yield trials were planted in 1983 on May 5 and July 15. In the spring-planted trial, good stands (greater than 75%), were obtained for Ladak, Maverick, and MT-O and MT-1 (two experimentals developed at SDSU). In the summer-planted trial, the best stand (45%) was exhibited by MT-1. Stands of Ladak, Vernal, Travois, and Teton were 42, 39, 36, and 24%, respectively.

#### Sheep RAM TEST STATION RESULTS J. M. Thompson

The spring and fall ram tests conducted at the Central Research Station in Highmore provides seedstock producers valuable information on their rams. This information allows them to evaluate their breeding and selection programs. In addition, the information is valuable to the commercial sheep producers who purchase these rams for their flocks. The fail test is primarily for the wool breeds and the spring test for meat type breeds.

In the 1982 fall test, 16 producers entered 67 rams and 12 producers entered 46 rams in the 1983 spring test.

Results of the most recent spring and fall tests are presented in Tables 19 and 20, respectively.

The following formula was used to index the rams in the spring test period: I = 60 x (ADG) + 30 x (weight per day of age) + 5 x (muscle score) - 5 x (fat score) - 5 x (soundness score).

The following formula was used to index the rams in the fall test period: I = 60 x (ADG) x 4.0 x (staple length in inches) + 4.0 x (clean wool in pounds) - 3.0 x (face covering score) - 4.0 x (skin fold score).

#### Horticulture-Forestry Department Central Research Station Report

#### Fruit

The fruit planting at Highmore enables SDSU to evaluate varieties and advanced selections under the conditions of central South Dakota. The plot is irrigated during periods of drought. Valiant grape, introduced by SDSU in 1982, has produced well at Highmore for several years. Dietz plum has been extremely prolific at Highmore. This small European type plum is self fertile. The home gardener in central South Dakota will find a single tree will produce an abundance of fruit for fresh use, canning, and jams. Rabbits caused serious damage to the fruit trees four or five years ago, especially on the apple and pear trees. Trees of two pears developed by SDSU are recovering from rabbit damage and now are growing well at Highmore. Luscious pear, introduced in 1973, is an excellent dessert pear which may be stored until December. The other pear is an Asian type pear, a kind of pear new to the western world but now coming into great demand in the USA. The South Dakota selection is highly flavored and stores well. We anticipate releasing this pear in 1986 or earlier.

Connell Red, Redwell, and Haralson apples are also in the fruit planting as is a rootstock study in which apples are grafted on Siberian roots (the commonly used apple roots in South Dakota) and M 7 roots (a dwarfing root). Rabbits caused a major setback in this study. We anticipate planting two new SDSU apple selections in 1984.

#### Woody Drnamentals

There were no new woody ornamental plant materials from the NC-7 Plant Introduction Program planted at the Station in 1983. No additional plantings are planned for 1984. A new project leader has been hired for the Ames, Iowa Plant Introduction Station. We expect some new woody plant materials will be available for planting at the Central Research Station in 1985.

Plantings of Re. Maple and Forsythia appear to be growing quite well at the Station. The release of the new winter hardy forsythia cultivar '<u>Meadowlark</u>' is scheduled for 1984. This will be a joint release with North Dakota State University.

Seed has been collected from an Amur Maple tree named Red Wing and will be distributed.

We hope to continue the evaluation of woody ornamental plants at the Station. Problems associated with the plantings continue to be rabbit and rodent damage and accomplishing the needed cultural practices for proper maintenance of the plant materials.

#### New Horticulture-Forestry Department Head

Dn January 1, 1984 Dr. Thomas D. Warner will become the new department head. Dr. Warner is a native of Indiana. He comes to SDSU from Kansas State University where he has held the position of Teaching Program Leader in the Department of Forestry and served as the Chairman of the Natural Resources Management Curriculum.

#### Soll Survey of Highmore Research Station G. D. Lemme

A soils map of the Highmore research station was prepared at a scale of 1:24,000 and 1:2,514 by Nilo Reber (SCS, Soil Scientist) and Gary Lemme using the Hyde County soil survey legend and one prepared specially for the station, respectively. The map, legend, map unit composition, classification, and soil properties are given in Figure 1, and Tables 21-24, respectively.

In most areas of the station, two major soils occur so closely intermingled or in such small areas that mapping them separately is not practical at the selected scale. Additional information can be obtained or the soils at an individual plot can be determined by contacting the Pedology section of the Plant Science Department.
