**1984 SOUTH DAKOTA VARIETY RECOMMENDATIONS,
CHARACTERISTICS, AND YIELD DATA:
SOYBEANS**

Robert G. Hall, Extension Agronomist - Crops

Joseph J. Bonneman, Assistant Professor - Crop Testing

Paul D. Evenson, Statistician

Successful soybean production is greatly affected by variety selection for a given growing area. This publication contains variety recommendations, descriptions, and yield data for soybeans.

Important factors in variety selection include yield, maturity, plant height, lodging resistance, and Phytophthora root rot resistance (See SDSU Soybean Traits Evaluated--All Entries). In the case of public varieties, additional information is available which may aid farmers in variety selection. Such information includes relative maturity, emergence, shattering, and iron chlorosis scores (see Regional Soybean Traits Evaluated--Public Entries).

It is important to realize that soybean varieties are classified according to various maturity groups. Maturity grouping is greatly influenced by latitude. Consequently, maturity group-00 varieties are best suited to Canada and extreme northern regions of the U.S., while maturity group-0 to early group-III varieties are suited to South Dakota, and group-IV through group-VIII varieties are suited to Iowa, Nebraska, and southward to the Gulf States.

In South Dakota the appropriate crop adaptation area (see map) for a given maturity group is as follows:

<u>Maturity Group</u>	<u>Crop Adaptation Area</u>
-----------------------	-----------------------------

- | | |
|--|--|
| 0 | D1, D2, D3, and northern counties of C1 and B2 |
| I | D1, D2, D3, C1, and B2 |
| II | Southern counties of B2 and C1, area D3, and northern counties of D4 and E |
| III | Those counties bordering the Missouri River in areas D4 and E |
| One should note that for some crop adaptation areas, there may be transition zones where varieties | |

VARIETY RECOMMENDATIONS

Variety recommendations (inside cover) are made annually by the Plant Science Department Variety Recommendation Committee. Recommendations for a given variety may vary from one crop adaptation area to another. Crop adaptation areas (see map) are based on soil type, elevation, temperature, and rainfall. Soybean varieties are recommended on the basis of growing season, average rainfall, disease frequency, and farming practices that are common to a given crop adaptation area.

of two maturity groups may perform similarly. In most cases, an earlier maturity group may be seeded in an adaptation area suited to a late maturity group. Generally, this is only practical where seeding has been delayed or some type of double cropping is used.

In many cases, farm location and management skills in one adaptation area resemble those in another area. Therefore, farmers should regard this fact when considering these recommendations.

A variety, either public or private, must be evaluated according to the minimum requirements discussed in **Recommendation Procedures** before it is eligible for recommendation.

Varieties are classified as "recommended," or "acceptable/promising." Varieties listed as "recommended" have exhibited a high level of performance. Those listed as "acceptable/promising" have either performed well but do not merit the "recommended" list or are new varieties which have shown a high performance level but have undergone limited testing.

Farmers should realize that **certified seed** is the best source of seed and the only way in which they can be assured of the genetic purity of the variety purchased. In addition, farmers should realize that inoculation of seed with the appropriate nitrogen-fixing bacteria is a good fundamental practice. Inoculation is generally needed if soybeans are seeded in soils not previously cropped with soybeans. However, on such soils there is no guarantee that inoculation in the current year will occur as a result of the inoculation of seed in previous years. Inoculation of seed at planting is a cheap means of increasing the percentage of plants that will fix nitrogen in the current crop year.

YIELD

All yield information is obtained from the SDSU Crop Performance Testing Program. One-year yields for varieties tested are included for each test location. Three-year averages are also included where varieties have been tested for 3 or more years. Yield comparisons should only be made on 3-year averages or on one-year averages. Comparison in yielding potential among varieties is best done by using 3-year averages.

Variety Recommendation Committee members include M.L. Horton (Chairman); R. G. Hall and C.E. Stymiest (Extension crops); J.J. Bonnemann and H.A. Geise (crop testing); F.A. Cholick and K. Sellers (spring wheat); J.L. Gellner (winter wheat); C.L. Lay and K. Grady (flax and soybeans); D. Reeves (barley, oats, and rye); C.W. Holland (forage crops); P. Weeldreyer (Extension irrigation); G. Buchenau, M. Ferguson, and W.S. Gardner (plant pathology); R.J. Pollmann (seed certification); and J.B. Weber (Foundation Seed).

GENERAL TEST PROCEDURES

Recommendation Procedures: Recommendations of both public and private varieties are based on a minimum of 3 years and 5 location-years for variety, yield, moisture, and maturity. Variety characteristics like height, protein, oil content, disease reactions, and lodging are considered when information is available.

Test Procedures: Standard 30-inch row spacings were used at all locations. Adjustments in seeding rates, on a pure-live-seed basis, were made to attain a final population of 140,000 plants per acre for all varieties and locations. All test plots consisted of 2-row plots, 16 feet long, with four replications. Varieties

were inoculated and a granular herbicide was banded over the row behind the press wheel. Additional herbicides and fertilization were dependent on each farm cooperator. Check varieties for each maturity group include Simpson and Weber for group-0; Weber and Corsoy 79 for group-1; Corsoy 79 and Mead for group-11; and Mead and Pella for group-111.

REGIONAL SOYBEAN TRAITS EVALUATED--PUBLIC ENTRIES

SDSU SOYBEAN TRAITS EVALUATED--ALL ENTRIES

Yield: Plots were harvested at 15% seed moisture or less and dried. Yields were calculated on a 13% moisture content basis, and expressed in bushels per acre.

Maturity: Entries were considered mature when 95% of the pods had turned brown.

Height: Height was measured from the soil surface to the top node of the main stem.

Lodging Score: Scores at maturity were based on average erectness of the main stem of plants within variety and location. 1 = all plants erect, 2 = slight lodging, 3 = lodging at a 45 degree angle, 4 = severe lodging, and 5 = all plants flat.

Phytophthora: Resistance of entries to race 1 was supplied by the entrant (private) or obtained from the USDA Uniform Soybean Tests, Northern States (public). Entries were designated as R = all plants resistant, S = all plants susceptible, M = mixture of resistant and susceptible plants, and X = data not available.

Regional evaluations of public soybean variety characteristics are conducted annually and reported by USDA as the Uniform Soybean Test, Northern States (Table 1). Character evaluations and locations include maturity (Brookings, SD), emergence (Ames, IA), shattering (Manhattan, KS), and iron chlorosis (Lamberton, MN). A discussion of these characteristic evaluations follows.

Maturity: Date when 95% of the pods have ripened. Maturity in days is reported as the number of days that a variety is earlier (-) or later (+) than Corsoy 79.

Emergence: Indicates the percentage of seeds which have emerged after 12 days from a 4 1/2-inch depth in sand maintained at 77 F. Scores include 1 = more than 85% emerged, 2 = 70-84% emerged, 3 = 45-69% emerged, 4 = 20-44% emerged, and 5 = 0-19% emerged. A score of 4 or 5 indicates the variety exhibits slow emergence. Such a score does not mean the variety will perform poorly.

Shattering: Indicates what percent of the pods open 2 weeks after maturity. Scores include 1 = no shattering, 2 = 1-10% shattered, 3 = 11-25% shattered, 4 = 26-50% shattered, and 5 = over 50% shattered.

Iron Chlorosis: Susceptibility evaluated on high pH soils range from 1 = little or no yellowing to 3 = moderate yellowing to 5 = severe yellowing.

NOTE: Rains and flooding prevented yield trials at Elk Point in 1984.

Table 1. Some characteristics of the public soybeans varieties included in the 1984 South Dakota crop performance tests (data was obtained from the uniform soybean tests - northern states).

#NS INDICATES THERE IS NO SIGNIFICANT DIFFERENCES AMONG VARIETIES.

ADDITIONAL VARIETY COMMENTS

Century: Slow emergence, fair resistance to iron chlorosis, adapted to Southeastern counties.

Corsoy 79: Susceptible to lodging and highly susceptible to iron chlorosis; best adapted to the James River Valley, East Central, and Southeastern counties.

Elgin: Slow emergence, fair iron chlorosis resistance, adapted to East central and Southeastern counties.

Evans: Quick emergence, moderately susceptible to iron chlorosis, best adapted to Northeastern and East Central counties.

Harcor: Susceptible to iron chlorosis, prone to shattering, best adapted to the James River Valley, East central, and Southeastern counties.

Hardin: Moderately susceptible to iron chlorosis, good shattering resistance, best adapted to Northeastern and East Central counties.

Hodgson 78: Slow emergence, fair resistance to iron chlorosis, best adapted to Northeastern and East Central counties.

Lakota: Susceptible to lodging, good resistance to iron chlorosis and shattering, best adapted to Northeastern and East Central counties.

Mead: Highly susceptible to iron chlorosis, slow emergence, prone to shattering, best adapted to Southeastern counties.

Nebsoy: Good emergence, moderately susceptible to shattering, high susceptibility to iron chlorosis, adapted to East central and Southeastern counties.

Pella: Moderately susceptible to iron chlorosis, good shattering resistance, adapted to extreme Southeastern counties.

Swift: Moderately susceptible to shattering, best adapted to Northeastern and East Central counties.

Simpson: Quick emergence, moderately susceptible to iron chlorosis, best adapted to Northeastern and East Central counties.

Weber: Good shattering resistance, fair resistance to iron chlorosis, best adapted to Northeastern and East Central counties.

Wells II: Slow emergence, moderately susceptible to iron chlorosis, prone to shattering, best adapted to upper James River Valley, East Central and Northeastern counties.
